The Universe Set

The set $S = \{\cdots 0, \frac{1}{2}, 1, \frac{3}{2}, 2 \cdots\} \cdot \hbar$

where s is the spin of a particle. represents our past, current and probably future understanding of the universe around us. As of the moment Currently we know:

- $s = \frac{1}{2}\hbar$ Describes all the matter in our universe.
- $s = 1\hbar$ Describes gauge interactions.
- $s = 0\hbar$ Responsible for giving mass.
- $s = 2\hbar$ Describes gravity (gauged?).
- $s = \frac{3}{2}\hbar$?? **Dark Matter?**

However, this magic set only describes $\approx 4.6\%$ of our total

universe.

• Long-Lived Particle Models

- ★ Gauge Mediated Supersymmetry Breaking (GMSB)
 - ▷ Next-to-lightest SUSY (NLSP) is **Neutralino** ($\tilde{\chi}_1^0$)
 - ▷ $eV - keV$ Lightest-SUSY particle (LSP) is **Gravitino** (\tilde{G}).
 - ▷ Gravitino is a Dark Matter Candidate.
- ★ General Gauge Mediation (GGM)
 - ▷ NLSP is a mixture of fermions (Bino, Wino, Higgsino).
 - ▷ Several SUSY particles can be NLSP.

• ECAL Resolution

- † ECAL timing resolution
 $\sigma_t < 500$ ps.
- † Use timing to identify
photons and electrons from
long-lived decay.

- ▶ Non-collision events like proton Beam Induced Background (BIM or Halos)/Cosmic/Anomalous spikes contribute towards delayed photons ECAL timing.
- ▶ Need to define a cleaning mechanism for identifying and rejecting non-collision events.

Features around $\phi = 0, \pm\pi$ and η -dependence shows that background sources originate from both collision and non-collision events.

We estimate these background by defining two Control samples.

In-time events Control Sample (IT-CS)

Out-of-time events Control Sample (OT-CS)

Control Sample (In-time Events)

IT-CS: > 2 Jets Events with photon ECAL time, $t \in [-1, 1]$ ns.

Control Sample (Out-Of-time Events)

OT-CS: 0 Jet Events with photon ECAL time, $t < -3$ ns
or $t > 2$ ns.

Events from above CSs provide a unique approach to estimate possible background contribution in signal.

Beam Halo Muons

- Proton beam interacting with gas/air particles in the beam pipe,
- Proton beam colliding with the collimators upstream prior to entering the CMS detector.

will produce energetic muons traveling parallel with main proton beam and showering in the Calorimeters.

Using Halo kinematics, We can tag and estimate halo photons produced from halo muons showering in ECAL as follows:

Halo Expected ECAL Time

$$t_0 = \frac{\rho}{c} = \frac{R}{\sin \theta} \frac{1}{c}, \quad t_{halo} = \frac{Z}{c} = \frac{R}{\tan \theta} \frac{1}{c}$$

$$\Delta t_H^{exp} = t_{halo} - t_0 = -\frac{R}{2c} \exp^{-\eta}$$

eta vs Ecal time

Additionally, using halo muon hits from CSC segment matched in ϕ to Superclusters in ECAL, we can additionally identify, tag and remove halo photon events with large timing.

Halo Photon Matching

$$\Delta\phi(CSCSeg, \gamma) = |\phi_{CSCSeg} - \phi_{\gamma}|$$

Satellite/Ghost Beam Halos

- Fill empty RF buckets.
- Trail main bunches by ≈ 5 ns.
- 10^{-5} protons compared to main bunches.
- Can contribute to main collision photons.
- Show a 2.5 ns pattern in EE,
- Tagged using $\Delta\phi(CSCseg, \gamma)$.

LHC LDM Proton Beam Profile

Halo Photon Event Properties

- Halo photons populate around $\phi = 0, \pm\pi$
- ECAL time mostly < -3 ns but can also arrive late(ghosts).
- Halo events most contain no jets (0-jet events).
- Rare cases can be associated with "pile-up" events.

Halo Photon Tagging Criteria

- Use $\Delta\phi(CSCseg, \gamma) < 0.05$ radians.
- Shower shape(
 $0.8 < S_{Major} < 1.65$ and
 $S_{minor} < 0.2$)

$$E_T^{\text{miss}}(\gamma)$$

PF-MET calculation fails to take into consideration E_T from out-of-time photons. We make PF-MET adjustment by taking into account the E_T of out-of-time photons for E_T^{miss} measurements. This new PF-MET is called $E_T^{\text{miss}}(\gamma)$.

As a result our signal selection criteria is defined as:

Signal Selection Criteria

SIGNAL: $\geq 1\gamma + \geq 2\text{Jets} + E_T^{\text{miss}} > 60, E_T^{\text{miss}}(\gamma) > 60 \text{ GeV}$

Assume similar distribution in earlier and delayed ECAL time for untagged non-collision events.

$$E_T^{\text{miss}} > 60 \text{ GeV}$$

$$\frac{D}{C} = \frac{B}{A}, \Rightarrow$$

	$E_T^{\text{miss}}(\gamma) < 60$	$E_T^{\text{miss}}(\gamma) > 60$
$t < -3 \text{ ns}$	A	B
$t > 3 \text{ ns}$	C	D

$$D = \frac{B}{A} \cdot C$$

Picture Explaining non-collision untagged background

ABCD Technique: Collision Background

Assume similar distribution in earlier and in-time, in-time and delayed ECAL time for collision events.

$$E_T^{\text{miss}}(\gamma) < 60 \text{ GeV}$$

	$E_T^{\text{miss}} < 60$	$E_T^{\text{miss}} > 60$
$t < -3 \text{ ns}$	B'	B
$ t < 2 \text{ ns}$	F'	F
$t > 3 \text{ ns}$	D'	D

$$\frac{Q}{D'} = \frac{F}{F'}, \Rightarrow$$

$$Q_d = \frac{F}{F'} \cdot D'$$

Using $Z \rightarrow ee$ events.

Background estimation is Data driven. Thus, most of a systematics come from signal, including:

Experimental Systematics

- Definition of Absolute or Zero time,
- ECAL time Resolution,
- Unclustered Energy,
- Jet energy scale,
- Jets energy resolution,
- Photon energy scale,
- Luminosity. We use standard CMS luminosity uncertainty.

Theoretical Systematics

- Choice of PDF.
- Re-normalization group equations.

Systematic Uncertainties

Source	Uncertainty(%)
Absolute time(Zero time)	10 ~ 6
Unclustered Energy	10 ~ 4
Photon Energy Scale	4 ~ 2
ECAL Time Resolution	5 ~ 2
Jet Energy Scale	9 ~ 3
Jet Energy Resolution	9 ~ 2
Luminosity	2.6
Choice of PDF	< 1

- Systematics is obtained by studying the effects of varying by a few amount of a particular source of systematic on the total number of objects passing object selection cuts.
